 TITLE : Hematopoiesis in the Bone Marrow of Donors After Giving Different Amounts of Blood.  
 ORIG. PUB. : V sb.: Aktual'n vopr. pereliv. krovi, Byp. 5, Leningrad, 1957, 7-14  
 ABSTRACT : The peripheral blood and bone marrow were studied in 81 donors of both sexes and of various ages after they had given 250 and 400 ml of blood 3 or 4 times within a period of 45 days. The Hb level fell by 3.7 to 8% and erythrocyte levels by 450,000 to 780,000 per mm<sup>3</sup>; the reticulocyte count increased slightly, especially in those cases in which 400 ml of blood was taken. No substantial difference was detected in the blood picture of initial donors as compared with that of donors which had given blood for a long time. A slight stimulation of erythroid and myeloid series

 ABSTRACT : was noted in the bone marrow of long-term donors. Later examinations (toward day 45) showed all indices to have returned to the initial values. Adequate functional capacity and adaptivity of the bone marrow are evident in the changing phases of hematopoiesis--proliferation, maturation and release of the mature cells. Inhibition of erythropoiesis prevailed the first day after the blood was taken; after 7 to 14 days stimulation was observed, and normalization of erythropoiesis was noted between the 30th and 40th day. With respect to leukopoiesis

TITLE: Modification of chrysotile asbestos by organopolysiloxane in an acoustic field

SOURCE: Zhurnal prikladnoy khimii, v. 38, no. 3, 1965, 510-515

TOPIC TAGS: asbestos, acoustic field, siloxane, carbon, nonmetal tensile strength

ABSTRACT: Chrysotile asbestos, which represents about 96% of the total asbestos mined in the USSR, is not acid resistant and absorbs large amounts of water, which impairs its technical value. Grafting of polyorganosiloxane radicals on the surface of the mineral considerably improves its chemical resistance and thermal and electric insulating properties. The grafting can be conducted in the medium of the agent to be grafted, or in its solutions, by means of an ultrasonic field.

Chemical analyses and IR spectra indicate the presence of carbon and of C-H bonds in the treated asbestos. Inasmuch as interplanar distances are

Card 1/5

L 48579-65

ACCESSION NR: AP5008803

not changed in the asbestos fibers after the treatment, according to the x-ray patterns, only surface modification of the fibers is assumed. The modification experiments were conducted with crude or graded chrysotile asbestos from the Bazhenovo deposit in the Urals, and with several organopolysiloxanes of various degrees of polymerization, as shown in Table 1.

4

Table 1. Carbon content in the modified asbestos samples (crude, treated for 1 hr)

A mixture of asbestos and organopolysiloxane (or its solution) was subjected to ultrasonic vibrations with a frequency of 19—21 kc and an intensity of about 7 W/cm<sup>2</sup>. Flowing water was used to cool the system. The operation was carried out in 30-min periods, with 15-min interruptions for cooling. The treated samples were thoroughly washed with benzene or toluene in a Soxhlet extractor and dried at 150° C.

Carbon content, water adsorption, resistance to hydrochloric acid and tensile strength of the fibers were determined both for initial and modified materials. Water absorption changed from 156% to 25% for the ethylpolysiloxane fluid-treated asbestos. Acid resistance is shown in Table 2.

Table 2. Effect of hydrochloric acid solutions on  
initial and modified chrysotile asbestos

L 48579-65

ACCESSION NR: AP5008803

Tensile strength of the modified asbestos was not impaired by the treatment. The authors suggest that active particles, which are formed from both the asbestos and organopolysiloxane molecules as a result of the destructive effect of cavitation, recombine, producing the attachment of poly-siloxane radicals to silicon or magnesium atoms by means of an oxygen bridge. The possibility of formation of similar derivatives for kaolin was previously demonstrated by the authors.\* Partial degradation of organopolysiloxanes by cavitation caused by ultrasonic vibration is confirmed by a certain decrease in the viscosity of the modifying agent. The acquiring of hydrophobic properties by the ultrasonically treated asbestos is explained by the formation of true chemical bonds between the mineral and the modifying agent, inasmuch as the mere adsorption of an organopolysiloxane on asbestos does not render the latter hydrophobic, in spite of a higher carbon content in the case of the adsorption. The higher acid resistance of the modified asbestos is explained by the better hydrophobic properties. This work was conducted in the Institute of the Chemistry of Silicates im. I. V. Gribenshchikov, Academy of Sciences USSR.

The mechanism of high temperature hydrogenation of aromatic hydrocarbons. I. Hydrides of anthracene and phenanthrene. B. I. Prokopenko, O. S. Pavlikova and L. A. Klimova. *J. Applied Chem. (U. S. S. R.)* 11, 523-527 (1938 French 24) (1938).—All expts. were carried out in a 1-l. autoclave at a const. H<sub>2</sub> pressure (160-20 atm.) in the presence of the Mo<sub>3</sub> catalyst prepared from Mo by treatment with H<sub>2</sub> under a pressure of 500 atm. at 450° for 12 hrs. Anthracene (10 g.) was hydrogenated at 200-300°, 320-40°, 370-410°, 410-50° and 440-50° for 60 min. in the presence of 10 g. of the Mo<sub>3</sub> catalyst, yielding 9,10-dihydroanthracene (mainly at 200°); 1,2,3,4-tetrahydroanthracene, syn-catahydronaphthalene (m. 73°) and perhydronaphthalene, depending on the exptl. conditions. The formation of 9,10-dihydroanthracene proceeded with great ease at 300°, but further hydrogenation of the latter compd. required a higher temp. On the other hand, the hydrogenation of tetra deriv., to the octahydride proceeded with such ease that in order to obtain the tetra deriv. it was necessary to cut down the reaction time and the amt. of catalyst. The hydrogenation of octahydronaphthalene, in turn, proceeded very slowly and an increase of temp. increased the yield of a liquid substance b. 280-300°. The product of complete hydrogenation of anthracene was perhydronaphthalene and the above liquid substance. Similarly to anthracene, increase of the reaction temp. increases the addn. of H<sub>2</sub> to phenanthrene, leading to the formation of perhydronaphthalene. The formation of dihydrophenanthrene was not observed. Under the same

conditions as those in the case of anthracene, phenanthrene underwent H<sub>2</sub> to form tetrahydronaphthalene to a lesser degree than anthracene. With an increase of temp., phenanthrene formed sym. octahydronaphthalene and finally, perhydronaphthalene (also name perhydronaphthalene). The yield of perhydronaphthalene was higher than that of tetrahydronaphthalene. Thirty-seven references. II. Hydrides of anthracene and the mechanism of their formation. B. I. Prokopenko. *Ibid.* 12, 9 (in French 1939).—Hydrogenation of anthracene at 330°, the conditions being as above, yielded sym. octahydronaphthalene and unsym. octahydronaphthalene, b. 63.5°. The yield of unsym. octahydronaphthalene increased with lowering of the temp. The di- and tetrahydronaphthalenes also yielded unsym. octahydronaphthalene. III. The composition of liquid product formed together with octahydronaphthalene and isomerization of octahydronaphthalene. B. I. Prokopenko, A. V. Pavlikova and A. M. Boguslavskaya. *Ibid.* 14, 515 (in French 1940).—The liquid product obtained from anthracene under the same conditions as before, contained sym. and unsym. octahydronaphthalene, perhydronaphthalene, "liquid perhydronaphthalene" and sym. octahydronaphthalene. Treatment of catalyst disclosed that the catalyst promotes the hydrogenation and isomerization processes. In this case the liquid product obtained was analogous to that obtained in the previous expts. Twelve references. IV. Isomeric transformations of octahydronaphthalene. B. I.

Pudsey and S. M. Bapnaikaray. [Ind. Eng. Chem. Res., 1979, 18, 109].—Under conditions of high-temp. hydrogentation in the presence of the Mo<sub>2</sub> catalyst, there is eq. rapid reaction w/  $\alpha$ -methylstyrene &  $\beta$ -methyl- $\alpha$ -methylstyrene, each of which is promoted by the catalyst. V. The composition of liquid polydienes previously obtained (cf. part III) was hydrogenated at 300° and 100-60 atm. pressure and after removal of the polydienes the liquid product was fractionated. The fractions b, 270-6° and 276-7° were dehydrogenated in the presence of the X-<sub>2</sub>-Al catalyst at 260-7°, yielding a mixt. of anethrene and phenanthrene. Therefore, the liquid polydienes contained polydienes.

Title : Thin structure of fluorescence spectra of aromatic hydrocarbons in frozen solutions

Periodical : Izv. AN SSSR. Ser. fiz. 18/6, page 673, Nov-Dec 1954

Abstract : Analytical data are presented regarding the structure of fluorescence spectra of aromatic hydrocarbons - coronene (consisting of seven condensed rings), 3,4-benzpyrene and pyrene - in frozen paraffinic hydrocarbon solutions (hexane, nonane). A strikingly thin structure of the fluorescence spectra, the characteristics of which depends upon the structure of the solvent, was observed in all cases investigated. Two USSR references (1951 and 1952).

Title : Effect of Solvent on Luminescence Spectrum of Aromatic Hydrocarbons at Low Temperatures

Orig Pub : Izv. AN SSSR. Ser. fiz., 1956, 20, No 4, 471-475

Abstract : Investigation of the spectra of fluorescence and phosphorescence of aromatic polycyclic hydrocarbons of the pyrene series at temperature of liquid air in frozen solutions in n-paraffins: 3,4,6,7-dibenzopyrene in n-heptane, 3,4-benzopyrene in n-heptane and n-octane, coronene in n-hexane, n-heptane, n-nonane, n-pentadecane and n-hexadecane. Fluorescence spectra consist of sharp lines as in acidic spectra. Spectra of coronene contain in addition to brilliant and sharp bands, bands that are sharp but weak which appertain to 1,12-benzoperylene (RZhKhim, 1955, 15746). Lines of fluorescence spectra of coronene solutions form doublets, relative intensities of components and  $\Delta \lambda$  clearly depend on the solvent, the following characteristics being apparent; 1) on transition from hexane to heptane ratio of component intensities

Card 1/2

USSR/ Physical Chemistry - Molecule. Chemical bond

B-4

Abs Jour : Referat Zhur - Khimiya, Nok, 1967, 10868

becomes inverted; 2) on transition from light to heavier solvents,  $\Delta \nu$  decreases from 84 to 38  $\text{cm}^{-1}$ ; in hexadecane the structure vanishes and the lines become diffused bands. With the exception of 3,4-benzopyrene, frozen solutions of the investigated substances show phosphorescence ( $\tau = 9$  sec. in the case of coronene), the spectrum of which is shifted, in relation to that of fluorescence, by  $6000 \text{ cm}^{-1}$  toward greater wave lengths. In n-paraffin solutions the bands are split; nature of splitting (number of components, intensity) depend on solvent. The authors consider that aromatic hydrocarbon incorporated in crystal lattice of solvent is distributed molecularly dispersed and not as microcrystals, since spectrum of crystal is diffused and has no fine structure. Noting that the observed splitting may be partially attributed to molecular Stark effect in the field of the crystal, the authors consider as a possible cause of fine structure of spectra superposition of lattice oscillations of the solvent.

EMISSION SPECTRUM LUMINESCENCE IN SOLVENTS AT LOW TEMPERATURE V. V. Klimova

Bull. Akad. Nauk SSSR Vol. 111 No. 11 (1957) In Russian

Certain polycyclic condensed aromatic hydrocarbons in solutions at normal pressures (petroleum benzene and xylene) when cooled to 77°K give fluorescent and phosphorescent spectrum consisting of narrow bands which are called lines. New photographs of these lines have been taken with instruments of greater resolving power and are reproduced. The lines are identified for different solvents and the effect of different solvents is considered. W. Burdick

AUTHORS: Shpol'skiy, E.V. and Alimova, L.A.TITLE: On the Problem of the Origin of Fine Structure in the Luminescence Spectra of Aromatic Hydrocarbons at Low Temperatures  $\lambda$ 

PERIODICAL: Optika i spektroskopiya, 1959, Vol 7, No 6, pp 852-854 (USSR)

ABSTRACT: The authors carried out (Refs 1-6) a series of investigations of the emission spectra (fluorescence and phosphorescence) of aromatic hydrocarbons dissolved in paraffins and frozen at the liquid-nitrogen temperature ( $77.3^{\circ}\text{K}$ ). The spectra of coronene, pyrene and 3,4-benzopyrene in normal paraffins from pentane to decane were studied in great detail. At low temperatures the bands were split into multiplets consisting of groups of lines of  $1-3 \text{ cm}^{-1}$  width. It was established (Refs 3-5) that these multiplet spectra can be represented as superpositions of several series of lines of different intensities displaced with respect to one another by definite "splitting intervals". Recently the authors studied the same spectra at  $20^{\circ}\text{K}$  and observed certain changes in them. For example in the case of coronene new lines were found and the distribution of intensities between the multiplet components was different from that at  $77^{\circ}\text{K}$ . The new lines observed at  $20^{\circ}\text{K}$  gave rise to vibrational series similar to those observed at the liquid-nitrogen temperature; in this way the number of such series

Card 1/3

67166

SOV/51-7-6-38/38

On the Problem of the Origin of Fine Structure in the Luminescence Spectra of  
Aromatic Hydrocarbons at Low Temperatures

in coronene increased to five or six. Moreover, separations between doublets observed in coronene (intervals of 86, 72, 38 and 42 cm<sup>-1</sup>), which were regarded (Refs 3-5) as characteristic of a given solvent were found in multiplets in all the solvents (Fig 1). Similar results were obtained at 20°K in the case of benzopyrene. The splitting intervals of benzopyrene were similar or identical with the intervals of coronene in various solvents. This means that the number and relative displacement of the series is governed primarily by the properties of the solvents, in spite of the fact that the series themselves are definitely due to electron vibrational transitions in the solute molecules. These and other experimental facts become clear if it is assumed that the series forming the multiplets belong to different spatially separated emitting molecules. Local differences of the crystal field are responsible for the multiplicity of the series and variations of the spectra. The following experiment confirms the above explanation. The fluorescence spectra were recorded using benzopyrene and pyrene solutions at 77°K, prepared in two ways: the usual rapid freezing and a slow freezing. In the latter case the emission spectrum was much weaker and its colour

Card 2/3

67166

SOV/51-7-6-28/38

On the Problem of the Origin of Fine Structure in the Luminescence Spectra of  
Aromatic Hydrocarbons at Low Temperatures

was somewhat different. Fig 2 shows the differences between the spectra of rapidly cooled (the upper part of Fig 2) and slowly cooled benzopyrene and pyrene (the lower part of Fig 2). On slow cooling the short-wavelength components disappear and the long wavelength ones are weakened. The central components are also weakened but they retain their positions. This shows that the fluorescence spectra of frozen solutions of hydrocarbons are sensitive to crystal structure changes. Acknowledgments are made to the Director of the Institute of Physical Problems, Ac. Sc. U.S.S.R., Academician P.L. Kapitza for making it possible to study these spectra at very low temperatures. There are 2 figures and 13 references, 7 of which are Soviet, 2 English, and 4 French.

TITLE:

Vibrational Analysis of the Phosphorescence Spectrum of  
Coronas (Vibratsionnyy analiz spektra fosforetsentsii  
koronena)

PERIODICAL:

Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1959,  
Vol 23, Nr 1, pp 23-28 (USSR)

ABSTRACT:

For a number of polycyclic aromatic hydrocarbons it was found that the difference of frequencies in phosphorescence and fluorescence spectra is almost equal. A vibrational analysis was impossible due to the broad indistinct bands and the fact that they almost converge. However, if a paraffin hydrocarbon is used as solvent, the bands are split into lines which are measurable within an error limit of  $2\text{-}3 \text{ cm}^{-1}$ . In this paper the phosphorescence spectrum was photographed simultaneously together with the fluorescence spectrum at an excitation by the mercury lines 3650 Å and 3135 Å. The cuvette was cooled with liquid nitrogen down to  $77.3^\circ \text{K}$ . The corona spectrum was photographed in various solvents, paraffin oil, heptane, octane, and pentadecane. In the figures adjoining it is shown that the corona bands in paraffin oil or ethyl alcohol are

Card 1/3

Vibrational Analysis of the Phosphorescence Spectrum 30V/48-23-1-5/36  
of Coronae

split in heptane or octane solution into lines which, however, run together already in octane. In pentadecane only very indistinct broad bands are visible, which already earlier (Ref 4) was ascribed to the ratio between the dimensions of the C axis of the solvent chain and the dimensions of the corona molecule. All spectra obtained represent three triplets which differ in their microstructure. The first triplet contains three groups of lines, each of them possessing 4 lines. Their distances within the frequency scale are equal in all three groups. The second triplet also comprises three groups, each of them possessing four lines. The distances vary in this case. The third triplet includes doublet-shaped groups of lines. In every solvent the spectrum may be represented as series which have equal frequency differences. Their distance varies only in the individual solvents. Accordingly, it is assumed that, if the emission spectrum of fluorescence was produced by the lowest level of the first state of excitation, each series indicates the structure of the vibrational level of the normal state. The phosphorescence spectrum shows quite the same features (Tables 1, 2 and Scheme. Table 2 according to Bowen and

Card 2/3

AUTHOR: Klimova, L.A.

TITLE: Absorption and luminescence spectroscopy of perylene at 20 and 4°K

SOURCE: Optika i spektroskopiya, v.15, no.3, 1963, 344-356

TOPIC TAGS: absorption spectrum, luminescence spectrum, molecular vibration, perylene

ABSTRACT: Although there have been many experimental and theoretical studies of the spectra of perylene ( $C_{16}H_{10}$ ), including the luminescence and absorption spectra in frozen solutions in normal paraffins at 77°K, hitherto there have been no studies of the solution spectra at 20 and 4°K. The present work is one of a series of studies of the absorption and fluorescence spectra of different substances at 20 and 4°K in normal paraffins, and was devoted specifically to recording and analysis of the spectra perylene. The spectra were recorded on a lab-assembled diffraction grating set-up. Instead of the 60 odd lines observed in the fluorescence spectrum of this compound in hexane at 77°K, at 4°K there were detected more than 220 lines, and analysis of the spectrum yielded 25 normal vibration modes, in contrast to the

Card 1/2

L 19976-63

ACCESSION NR: AP3007271

8 modes deduced from the spectrum at 77°K. The great narrowness of the lines made it feasible to perform the analysis not only in the long wavelength region but also in the region of the second electronic transition. It was also noted that upon deep cooling the character of the multiplets composing the frozen solution spectrum changes, which made it possible to infer additional information on the structure and characteristics of the perylene molecule and the origin of the quasi-line spectra. The fluorescence and absorption spectra are reproduced, and the line wavenumbers, intensities, and attributions are tabulated. Diagrams of the head multiplets are given. The results of the study show that the Shpol'skiy frozen solution method makes it possible to obtain accurate and reliable information on the normal modes in organic molecules. "The author takes pleasure in acknowledging her gratitude to E.V.Shpol'skiy for his guidance and interest in the work." Orig.art.has: 6 figures and 3 tables.

AUTHOR: Klimova, L. L. (Engineer)

TITLE: Strela-2 sea-going hydrofoil

SOURCE: Sudostroyeniye, no. 5, 1963, 9-12

TOPIC TAGS: hydrofoil craft, shipbuilding engineering/Strela-2 hydrofoil craft

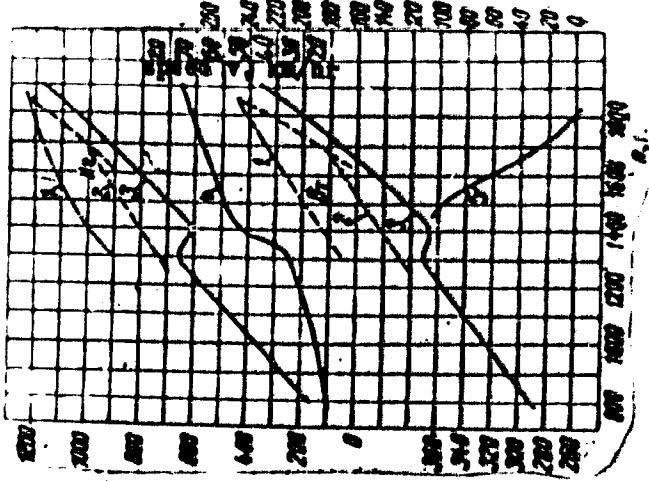

ABSTRACT: The Strela-2, a Soviet sea-going hydrofoil, has a riveted hull made of duraluminum alloys D16-T (plating) and D16-T (shapes). [The nearest US equivalent is the wrought aluminum alloy 2024.] It is built by the transverse-longitudinal frame system, with the midship frame spacing at 500 mm and the spacing of longitudinals at 200—260 mm. The frames consist of plates and angles (bulb angles in the foreship and webs near the foils). The shell plating is 3—5 mm and the deck plating is 2—4 mm thick. The struts and foils are of stainless steel with a hollow construction. The foils are protected by light-alloy pipe guards to prevent their being damaged during mooring.

Prague, Pracovni Lekarstvi, Vol 19, No 2, Mar 67, p 88

Abstract: A review of chemicals causing acute bronchitis is presented. Practical experience gained with such cases at the Clinic for Occupational Diseases at Brno during the last 10 years is described. The most serious cases were caused by phosgene, diazomethane, and by polyurethanes. These can cause damage that appears 2 years after the period of the last exposure. No references. Submitted at the Seminary of Occupational Diseases organized by the Clinic for Occupational Diseases at the JE Purkyne University at Brno on 15 Sep 66.

✓ Increasing the chemical resistance of glassware. N. A. Klimova and I. I. Bril'. U.S.P.R. 109,041, Oct. 25, 1957.  
To increase its chemical resistance, into a glass article, either cold or heated, is placed a pellet of 1 of the following salts or their mixt.: Fe or Al NH<sub>4</sub> sulfate, Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>3</sub>, or NH<sub>4</sub>Cl, and the article is placed in the furnace at the annealing temp. TITLE:

Application of the Diethylditiocarbamate of Sodium for the Separation of Uranium from Some Elements (Primeneniye diethyl-ditiocarbamata natriya dlya otdeleniya urana ot nekotorykh elementov)

PERIODICAL:

Vestnik Moskovskogo universiteta, Seriya matematiki, mehaniki, astronomii, fiziki, khimii , 1958, Nr 3, pp 217-220 (USSR)

ABSTRACT:

The quantitative extraction of the uranium-di-ethyl-di-tio-carbamate by organic solvents is attained for pH 6.5 - 7.5 . A complete extraction of uranium from a layer of the organic solvent into water takes place under influence of nitric acid (1 : 20) or of a saturated solution of ammonium carbonate. The authors develop a method for the separation of small quantities of uranium (one-hundredth part of one mg) from quantities of iron being 100 times greater. They discuss the possibility to obtain uranium and vanadium by extraction of V-diethylditiocarbamate from acid solutions for pH 0.4 - 0.5 .

TITLE: New method of synthesizing ammine borine, and its properties

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 8, no. 1, 1963, 66 - 68

TEXT: Ammine borine was synthesized by reaction between  $\text{NH}_3$  and  $\text{B}_2\text{H}_6$  in polar solvents according to  $\text{B}_2\text{H}_6 + 2\text{NH}_3 \rightarrow 2\text{NH}_3\text{BH}_3$ . The pure gases  $\text{B}_2\text{H}_6$  and  $\text{NH}_3$  were introduced at room temperature into the solvent (ether, dioxane, or water) saturated with  $\text{NH}_3$ , continuously stirred for 3 - 4 hrs. Water proved effective as a reaction medium.  $\text{NH}_3\text{BH}_3$  is crystalline and has an orthorhombic, face-centered lattice with the parameters:  $a = 7.22$ ;  $b = 7.38$ ; and  $c = 5.23 \text{ \AA}$ . The density of  $\text{NH}_3\text{BH}_3$  briquetes compressed at 2000 - 5000 kg/cm<sup>3</sup> is 0.73 g/cm<sup>3</sup> (density calculated from the parameters: 0.74 g/cm<sup>3</sup>). The melting point is  $104.5 \pm 0.5^\circ\text{C}$ . The solubility of  $\text{NH}_3\text{BH}_3$ , expressed in g/100 ml, is 33.6 in water, 6.5 in alcohol, 0.76 in ether,  
Card 1/2

B1.19/B186

## New method of synthesizing... .

0.5 in dioxane, 0.04 in benzene, 0.03 in toluene, and 0.02 in carbon tetrachloride. In aqueous solution  $\text{NH}_3\text{BH}_3$  is comparatively stable; in ~ 2.5% solution, 0.5 - 0.9% of the  $\text{NH}_3\text{BH}_3$  is hydrolytically split after 24 hrs standing at room temperature.  $\text{NH}_3\text{BH}_3$  can reduce gold, palladium, silver and copper, but also iron and nickel, from the solutions of their salts to the metallic state. Solid  $\text{NH}_3\text{BH}_3$  splits off hydrogen on heating: 1.5% at  $50^\circ\text{C}$ , 10 - 20% at  $75^\circ\text{C}$  after 6 hrs, about 33% at  $\sim 105^\circ\text{C}$ , ~ 50% at  $150^\circ\text{C}$ , and 60 - 70% at  $300^\circ\text{C}$ . At  $500^\circ\text{C}$  and over, the hydrogen is completely split off, and BN is formed. There are 1 figure and 1 table. The English-language references are: S. J. Shore, R. W. Parry. J. Amer. Chem. Soc., 77, 6084 (1955); S. J. Shore, R. W. Parry. J. Amer. Chem. Soc., 80, 1, 8 (1958).

TITLE: Brief Communications. The Catalytic Oxidation of Acetophenone Into Benzoic Acid

PERIODICAL: Khimicheskaya nauka i promyshlennost', 1959, Vol 4, Nr 6, pp 799-800 (USSR)

ABSTRACT: The solid acetophenone from phenol-acetone plants is now used as fuel, in the form of phenolic tar. For the preparation of benzoic acid, the above acetophenone was catalytically oxidized both in vapor and in liquid phases. In the vapor phase, oxidation was carried out with air oxygen over a mixture of Va and Mo oxides, tin vanadate, supported on silica gel and chamotte; molar ratio of acetophenone-air 1:30, 1:60, between 200 and 300°. Benzoic acid (32%), maleic acid, and CO<sub>2</sub> were identified. In the liquid phase, oxidation was carried out with air and with pure oxygen, at normal pressure, over Mn, Co, Cu resinates and stearates. The best results were

Card 1/2

Brief Communications. The Catalytic  
Oxidation of Acetophenone Into  
Benzoic Acid

77289  
SOV/63-4-6-23/37

obtained by using Mn resinate as catalyst. The optimal conditions were: 150°, rate of oxygen 5 l/min, the ratio catalyst-acetophenone 2 g:1 g/mole. The conversion was 60-65% and the yield 70-75%. Benzoic acid, formic acid, formaldehyde, maleic acid, and CO<sub>2</sub> were identified.

Purified acetophenone was used in both cases (98.5-99% pure). Technical acetophenone inhibited the oxidation. The method of separation of benzoic acid from the reaction products was a preliminary distillation of recovered acetophenone, followed by extraction of benzoic acid with hot water. After recrystallization, the benzoic acid has mp 122° and 99.5% concentration. The yield by the above process was 83%. There are 4 figures; and 3 references, 2 Soviet, 1 U.S. The U.S. reference is: H. A. Riley, A. B. Gray, Org. Synthesis, 15, Nr 9, 67 (1935).
